3	Problem 3	5

§0 Problems

1. Let ABC be a right triangle with right angle at A , $AB = 21$, and $AC = 20$. Let D be the midpoint of \overline{AC} , ω_1 be the circumcircle of $\triangle ABD$, and let ω_2 be the circle with diameter \overline{AC} . Let ω_1 and ω_2 intersect at A and E . Let ω_1 intersect BC at B and K , and let ω_2 intersect BC at C and L . Let EK and the tangent to ω_1 at D intersect at M . Let EL and BD intersect at N . The circumcircle of $\triangle DMN$ has a radius of length $\frac{m}{n}$, where m and n are relatively prime positive integers. Find $m + n$.
2. In triangle ABC with $\angle A = 60^\circ$, let B' be the reflection of B over AC , and let C' be the reflection of C over AB . Let $B'B$ and $C'C$ intersect at D , and let $B'C$ and $C'B$ intersect at E . Let DE and BC intersect at F . Show that AF bisects $\angle BAC$.
3. Let ABC be a scalene right triangle with right angle at A . The incircle ω of $\triangle ABC$ touches sides \overline{BC} , \overline{CA} , and \overline{AB} at points A' , B' , and C' , respectively. Let ω intersect AA' at A' and D , and let E and F be the reflections of A' over points B' and C' , respectively. Let K be the foot of the perpendicular from E to $A'F$, and let L be the foot of the perpendicular from F to $A'E$. Show that $B'C'$, KL , and the line perpendicular to AA' at D are concurrent.

§1 Problem 1

Let ABC be a right triangle with right angle at A , $AB = 21$, and $AC = 20$. Let D be the midpoint of \overline{AC} , ω_1 be the circumcircle of $\triangle ABD$, and let ω_2 be the circle with diameter \overline{AC} . Let ω_1 and ω_2 intersect at A and E . Let ω_1 intersect BC at B and K , and let ω_2 intersect BC at C and L . Let EK and the tangent to ω_1 at D intersect at M . Let EL and BD intersect at N . The circumcircle of $\triangle DMN$ has a radius of length $\frac{m}{n}$, where m and n are relatively prime positive integers. Find $m + n$.

Solution. Let $P = BD \cap EM$. Note that $\angle MDN = \angle DAB = 90^\circ$. Then note that

$$\angle NEM = \angle LEA + \angle AEK = \angle LCA + \angle ABK = 90^\circ$$

implying $MDNE$ is cyclic with \overline{MN} the diameter of its circumcircle. Thus it suffices to find $\frac{MN}{2}$.

Claim. $\triangle NEP \sim \triangle BAC$ and $\triangle NEM \sim \triangle BAD$.

Proof. Note that

$$\angle CLE = \angle CAE = \angle MDE = \angle MNE$$

so $BC \parallel MN$. Thus $\angle DNM = \angle DBC$. Since $AD = ED$, $\triangle ABD \cong \triangle EBD$ and

$$\angle MNE = \angle MDE = \angle DBE = \angle ABD$$

implying the desired similarities. □

Therefore

$$\frac{MN}{2} = \frac{BD \cdot AE}{4AL} = \frac{[ABD]}{AL} = \frac{AB \cdot AD}{2AL} = \frac{[ABC]}{2AL} = \frac{BC}{4} = \frac{29}{4}$$

and $m + n = \boxed{033}$. ■

§2 Problem 2

In triangle ABC with $\angle A = 60^\circ$, let B' be the reflection of B over AC , and let C' be the reflection of C over AB . Let $B'B$ and $C'C$ intersect at D , and let $B'C$ and $C'B$ intersect at E . Let DE and BC intersect at F . Show that AF bisects $\angle BAC$.

Solution. Let $P = BC \cap B'C'$ and $Q = DE \cap B'C'$. First, note the angle condition implies that B' , A , and C' are collinear. Hence $B'C'$ is the exterior angle bisector of $\angle BAC$ and

$$\frac{AB}{BP} = \frac{AC}{PC}.$$

It's well known by Ceva and Menelaus that

$$-1 = (B', C'; P, Q) \stackrel{E}{=} (C, B; P, F) = \frac{CP}{BP} \div \frac{CF}{BF}.$$

Therefore

$$\begin{aligned} \frac{AC}{PC} \cdot \frac{BP}{AB} \cdot \frac{CP}{BP} \div \frac{CF}{BF} &= -1 \\ \frac{AC}{AB} &= \frac{CF}{BF} \end{aligned}$$

implying AF bisects $\angle BAC$. ■

§3 Problem 3

Let ABC be a scalene right triangle with right angle at A . The incircle ω of $\triangle ABC$ touches sides \overline{BC} , \overline{CA} , and \overline{AB} at points A' , B' , and C' , respectively. Let ω intersect AA' at A' and D , and let E and F be the reflections of A' over points B' and C' , respectively. Let K be the foot of the perpendicular from E to $A'F$, and let L be the foot of the perpendicular from F to $A'E$. Show that $B'C'$, KL , and the line perpendicular to AA' at D are concurrent.

Solution. Let $H = B'K \cap C'L$ and $P = B'C' \cap KL$. Note that $\angle C'A'B' = \angle C'B'A = 45^\circ$, implying $\triangle A'EK$ and $\triangle A'FL$ are isosceles right triangles. Thus $A'E \perp B'K$ and $A'F \perp C'L$.

Claim. A is the circumcenter of cyclic quadrilateral $B'C'KL$.

Proof. Since $\angle KB'L = \angle KC'L = 90^\circ$, $B'C'KL$ is cyclic with \overline{KL} the diameter of its circumcircle Γ . Note that $AB' = AC'$ and $\angle B'AC' = 90^\circ = 2\angle B'KC'$, so A is the center of Γ . \square

Since $\angle A'B'H = \angle HC'A' = 90^\circ$, H is the antipode of A' on ω and $\angle A'DH = 90^\circ$. By Brocard's theorem on Γ , $HP \perp AA'$, implying D , H , and P are collinear, as desired. \blacksquare
